Factors to consider

Çöltekin, A. 2019. "What Contributes to the Complexity of Visuospatial Displays?" In Abstraction, Scale and Perception. International Cartographic Association Joint Commission Workshop, 1–2.

Task type matters

Result of a study

- rainbow better than other tested color schemes
- mixed or neutral
- rainbow worse than other tested color schemes

Conclusions

- visualization community gradually moved away from using the RC, in other sciences the RC is still prevalent;
- the RC supports retrieving values -> the hues are highly discriminable,
- RC is not great for understanding patterns -> it generates false boundaries and distorts distances,
- RC is definitely not a good fit to show order in values
- if one must opt for the RC, a legend is an essential element to support users.

Take away

- make informed color design choices based on theory of colors and empirical evidence
- not every eye-grabbing color scheme is a correct choice
- not every popular color design is correct one
- not every default setting in software is the correct one
- make use of online support

Online support

DATA VISUALISATION RESOURCES

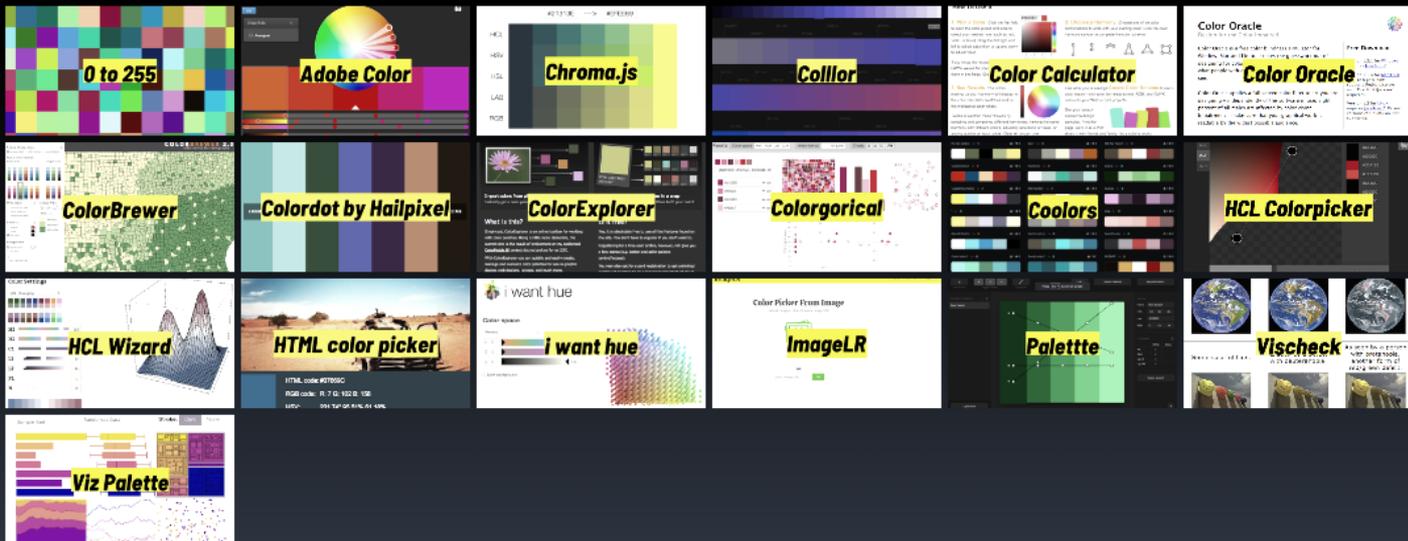

This is a collection of some of the many data visualisation (and related) tools, applications, toolkits, libraries, platforms, and packages.

Organised loosely around several categories, based on the best-fit descriptive characteristic or primary purpose, this collection has been curated since around 2010 to provide readers with as current and as comprehensive a view as possible of the visualisation technology landscape. The featured image above is a screenshot of the previous iteration of this resources catalogue, which was the most popular page on this website for many years.

COLOUR

This is a collection of tools for generating and editing colour palettes, as well as practical, theoretical, and inspirational sources of guidance.

SPECIALIST

This is a collection of design, presentation, publishing and niche resources that enhance the visualisation development workflow.

Rainbow Dash: Intuitiveness, interpretability and memorability of the rainbow color scheme in visualization

Izabela M. Gołębiewska, Arzu Çöltekin

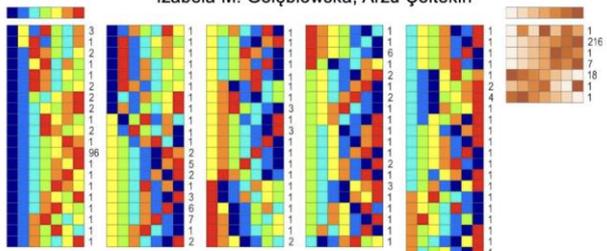

Figure 1. Tested color schemes (top row) and responses to T1: order hues (in columns below). Each row shows a unique sequence provided by at least one participant (counts are shown next to each set). Participants ordered the colors from "min to max" (left to right) purely based on their perceptual associations for the seven hues. We see 101 different orders for the rainbow and seven for the sequential schemes. The 'correct' sets are shown on top.

Abstract—After demonstrating that rainbow colors are still commonly used in scientific publications, we comparatively evaluate the rainbow and sequential color schemes on choropleth and isarithmic maps in an empirical user study with 544 participants to

ABSTRACT

Rainbow color scheme is popularly used across the board in many scientific disciplines for visualizing data, yet heavily debated in visualization literature. In this paper, we first report an interdisciplinary visualization survey examining the prevalence rainbow color scheme use in scientific publications including a temporal analysis. Then we consolidate findings from empirical studies on the subject to better understand why and precisely when the rainbow color scheme might impair human performance with visualizations. Consequently, we systematically document and analyze the consequences of using the rainbow color scheme based on over 37,000 figures in 11,808 papers in information visualization, neuroscience, hydrology, geography, remote sensing and planetary science. Our findings reveal that while the rainbow scheme appears less and less in visualization-related publications, it remains popular in other scientific domains including remote sensing and planetary sciences (strikingly fourteen times more frequent in remote sensing and planetary sciences than in information visualization outlets). We also find that conflicting findings about human performance with the rainbow color scheme is most likely explained by what the users are asked to do with it (i.e., task type). We detail and typify tasks used in the related empirical work in an effort to organize the current understanding on the subject, and translate it to practicable recommendations. We believe our review and analyses bring clarity and nuance to "the rainbow debate" and enable better-informed visualization advice.

1. Introduction

The rainbow (spectral) color scheme (RC) is commonly used for color

-ArcGIS or QGIS- for choropleth maps). Possibly because of these mismatches between theory and practice, the RC has been repeatedly a subject of research and debate in visualization communities (e.g. Bor-
